

Parallel Password Recovery Pro Crack [NEW]

i tried two different dictionaries with combinations of the following settings: dictionary size (number of passwords) dictionary size (number of words) word mutation passwords length (minimum, maximum, range) passwords (alphabet, number) passwords length (minimum, maximum, range) passwords mutation (alphabet, number) passwords length (minimum, maximum, range) words mutation (alphabet, number) words length (minimum, maximum, range) my attempts at cracking vm passwords were slightly different. for this, i used the virtual machine container file that parallels creates. this container file is smaller than the virtual machine file, and has the same content. thus, we can successfully brute-force recover the vm password, using a dedicated dictionary with custom settings. the results of a gpu-assisted brute-force attack can be seen below. the first number in parentheses is the average of 10 tries, the second one is the fastest result (the average of the best 10 tries). the third number is the average time per password, the fourth one is the fastest time per password. the same applies to the brute-force attacks using a virtual machine container file as a target. the container file can be used to brute-force recover the original vm password. if the vm password is secured using a strong hash algorithm (like sha256), the container file can be cracked even with relatively weak dictionary settings. for example, with 1,000 password attempts per second and an average dictionary length of 4 characters, the brute-force attack using a dictionary with 1,000 passwords and 2,000 words is not able to find the correct password.
